If more than one search is submitted, please prioritize searches in order of need.

Please provide a detailed statement of the search topic, and describe as specifically as possible the subject matter to be searched. Include the elected species or structures, keywords, synonyms, acronyms, and registry numbers, and combine with the concept or utility of the invention. Define any terms that may have a special meaning. Give examples or relevant citations, authors, etc, if known. Please attach a copy of the cover sheet, pertinent claims, and abstract.

Title of Invention: Electromagnetic Brake assembly and supply power

Inventors (please provide full names): Conny Johansson; Lars Nysgren;
Bruno Slettenmark

Earliest Priority Filing Date: 9/11/2002

For Sequence Searches Only Please include all pertinent information (parent, child, divisional, or issued patent numbers) along with the appropriate serial number.

Problem is an electromagnet is operated by DC (direct current) but interrupting the DC does not fully return the electromagnet to its original state (hysteresis).

Applicants solve the problem in 2 ways. different

① An AC source (alternating current) is connected to the electromagnet to reduce the residual magnetism by varying the AC.

② A capacitor and resistor are connected in parallel with the electromagnet to reduce residual magnetism.

Copy of application attached and labeled.

ABSTRACT

PURPOSE: To efficiently use the **power** from an **electromagnetic** type
retarder that is outputted during the **braking** operation of a vehicle as
the **power** supply for **charging** a battery by using a **capacitor** having a
large **capacitance**.

CONSTITUTION: An output from a retarder 1 for regenerating the **power**
during the **braking** operation of a vehicle is supplied to an electrical
double-layer **capacitor** 5 through a rectifier 16 and a diode 52 is
connected in such a direction that **charge** is led to a battery 3 from the
capacitor 5. Therefore, the diode 52 is reversely biased under the normal
condition and **power** supply from the battery 3 by self-discharge of the
capacitor 5 is suspended, but when an engine is started, a relay B closes
due to the operation of a key switch 6 and the **capacitor** 5 is **charged**
by the battery 3.

10, 1982 (19820710)

ABSTRACT

PURPOSE: To detect a **braking** condition through plugging accurately by determining reference voltage from a current detecting means by currents flowing under a locking condition of a motor during the operating time of a monostable multivibrator.

CONSTITUTION: When a switch not shown is changed over, **electromagnetic** contactors 5, 6 are each switched to the constantly-closed contact b side and the constantly-opened contact c side, and brought to plugging conditions, and currents by electromotive force flow through armature winding 3 through a plugging diode 7. In this case, the output of a comparator 20 is (1) because the **charging** voltage of a soft start **capacitor** 18 is small - that is, a conduction ratio is smaller than set value - due to the functioning of a clear circuit, etc. not shown responding to the action of a changeover switch owing to just after changing over. Since the magnitude of source currents during the operating period of the monostable multivibrator 16 becomes larger than reference value on account of the short circuit of the armature winding 3 by the diode 7 at the same time, the output of comparators 13, 49 is both (1), base currents are supplied to a transistor 51 and the transistor 51 is at on, and plugging can be detected.

JOURNAL: Section: E, Section No. 112, Vol. 06, No. 103, Pg. 166, June 12, 1982 (19820612)

ABSTRACT

PURPOSE: To precisely detect plugging **brake** condition without being affected by variations in temperature and **power** voltage, by a method wherein commutating **capacitor** voltage at the time of interrupting a thyristor chopper circuit is detected and the conductive rate of the chopper circuit is also detected.

CONSTITUTION: With **electromagnetic** contactors 3, 4 changed over at t=0, the voltage at the output point C of a reset soft start circuit 9 rises from the minimum value as shown in i, namely, the conductive rate of a chopper 1 also rises. The voltage at the output point B of a reference signal circuit 11 is decided by the voltage at a point C and the input voltage in a plugging detection circuit 14 decreases as shown in ii,

plugging **brake** starts at $t=t(\text{sub } 4)$ and when an armature winding 2b is in the, short-circuit condition, the **charge** voltage of a commutating **capacitor** 1d rises and the voltage after a vibrating phenomenon becomes more lower. Namely, the voltage (input voltage of the circuit 14) at the output point A in a **capacitor** voltage detector 12 at the time of interrupting the chopper 1 becomes lower than ii at $t=t(\text{sub } 4)$ as shown in iii, accordingly, detection is made to know that the circuit 14 is under plugging **brake** to act to decrease the electric potential at a point E and the conductive rate of the chopper 1 is controlled so as to be lower.

Abstract (Basic): WO 200066388 A1

NOVELTY - The energy accumulation and recuperation of vehicle are done, in points of electric contact system using **capacitor** bank, during motion and **braking** of motor vehicle.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for the energy accumulation and recuperation device.

USE - For energy accumulation and recuperation in different types of motor vehicles (MV) driven by electric motors or in combination with hybrid motor vehicles such as electric cars, trolley busses, trams, electric train.

ADVANTAGE - The **capacitor** fitness is not determined by number of **charge** -discharge cycles, as a result of which they are very much more durable than the accumulators. The efficiency of capacitors is much higher than that of accumulators and is equal to nearly 100%. Unlike the accumulators and fuel cells, capacitors can be **charged** and discharged exceptionally quickly for less than a second, which enables giving-off and intake of large currents towards and from the drive electric motors which in turn ensures great acceleration of the MV, without need of increasing the **power** of energy source. By using

capacitors, starting and reaching maximum speed are achieved without prior switching-ON of primary **power** source of motor vehicle. Enables greater freedom and maneuverability of the motor vehicle fed by electric contact systems, thereby reduces energy consumption for motor vehicle motion. Facilitates to remove the electric contact system above the basic part of route and replace it with separate points thereby avoids limitations concerning the height of transported cargo, thereby puts and end to spoiling the look of streets and squares with hanging electric contact system. The electric contact system is situated under the ground, thus it is naturally shielded and also additionally shielded through metal cover of cables thus avoiding **electromagnetic** pollution.

DESCRIPTION OF DRAWING(S) - The figure shows the perspective diagram explaining connection in case of two wires of electric contact system situated transversely on the road.

ABSTRACT

PROBLEM TO BE SOLVED: To provide an inexpensive **brake** device for combined operation allowing a **brake** instruction transmitting time to be shortened even in the combined operation of an air car and an electric car.

SOLUTION: In an electric car side re-reader 10, a **brake** instruction for the electric car is converted into an electric signal by using a specified conversion factor, and transmitted to an air car side re-reader 9 through an electric cable 11a. The air car side re-reader 9 converts the received electric signal inversely to a target **brake** pressure value by using a specified conversion factor. Then, according to an automatic **electromagnetic brake** system, a solenoid supply and exhaust valve 8 is **energized / deenergized** so that an actual BP pressure follows the target **brake** pressure value. Also when the **brake** instruction is transmitted from the air car to the electric car, the actual BP pressure is converted to an electric signal by using the conversion factor, and the electric signal is transmitted to an electric car side via an electric cable 12a.

ABSTRACT

PURPOSE: To shorten the torqueless time following the operation stoppage of a chopper during a transitional period from regenerative **braking** to reverse rotation **braking** by shortening the transitional period as much as possible.

CONSTITUTION: A transitional period from regenerative **braking** to reverse rotation' **braking** is shortened by stopping the operation of a chopper by turning of a transistor TM a fixed period after the coil MG of a regenerative **electromagnetic** switch is **energized** following the completion of the regenerative **braking** and, at the same time, starting the operation of the chopper for reverse rotation **braking** by turning on the transistor TM immediately after the closing state of a contact mg is detected by means of an operation detecting section 12.

ABSTRACT

PURPOSE: To suppress the slipping in a state that a towing force is held by detecting that the rotating speed of a wheel is a predetermined value or less and **energizing** an **electromagnetic** coil disposed oppositely to rails when a power running command is output.

CONSTITUTION: An **electromagnetic** coil 3 is mounted at a truck 2 oppositely to rails 1, and **energized** by **energizing** means 4. Speed comparing means 6 detects a rotating speed V, compares it with a set predetermined speed value Vset, and outputs a '1' signal to an AND circuit 7 when it is the value Vset or less. Then, it inputs the command from command means 5 and further inputs the outputs from the means 6, it outputs the '1' signal to an AND circuit 8. Then, when the circuit 8 inputs the '1' signal, it outputs a close signal to a switching circuit 4. The circuit 8 outputs the close signal to the circuit 4 even when it inputs the emergency **brake** command B from the means 5. Thus, the slipping at a low speed at the time of power running can be effectively prevented.

ABSTRACT

PURPOSE: To enhance generation efficiency or fuel consumption by interposing a retarder for recovering power **electromagnetically** from **brake** energy between a clutch and a speed change gear.

CONSTITUTION: Rotor 3 of retarder 2 is coupled with the output shaft of a clutch 13 for transmitting/interrupting engine torque, and a field section 41 is disposed on the inside of outer peripheral poles 31, 32 whereas an armature 4 is disposed on the outside thereof. When a vehicle is braked, the field section 41 is conducted to excite the poles 31, 32 thus taking out **brake** power from the armature 4. When the engine is started or accelerated, the field section 41 and the armature 4 are conducted to drive the retarder 2 through a motor thus **energizing** engine torque.

ABSTRACT

PURPOSE: To prolong the running distance of an electric automobile for one **charge** of a battery by a method wherein the shortage of a **braking** force obtained by regenerative **braking** and hydraulic **braking** against an instructed **braking** force is filled with a **braking** force supplied from an **electromagnetic braking** apparatus.

CONSTITUTION: In order to **brake** an electric automobile, a controller 20 determines a necessary **braking** force FA in accordance with the magnitude of a **brake** signal. On the other hand, the controller 20 obtains the **charging** status of a battery and determines the magnitude of a regenerative **braking** force in accordance with the **charging** status. Then a chopper circuit 22 is controlled by the controller 20 in accordance with a force value obtained by reducing the regenerative **braking** force and the hydraulic **braking** force of a hydraulic **braking** apparatus from the

necessary **braking** force. Therefore, an **electromagnetic brake** 24 generates a **braking** force which is determined by the controller 20 and the chopper circuit 22 in accordance with the necessary **braking** force and the regenerative force and **brakes** wheels through a decelerating mechanism 12 and a wheel shaft 10.

ABSTRACT

PURPOSE: To complete accurately insufficiency of electric **braking** force with **braking** force of a liquid **brake** in the **braking** device of the rolling stock car by a method wherein when an electric **brake** becomes to invalid, output liquid pressure of an electropneumatic converter is made to zero.

CONSTITUTION: **Braking** commands applied to command lines 2, 3, 4 are transmitted to an electric **brake** equipment 13 through a D-A converter 12. The electropneumatic converter sends out a liquid having pressure corresponding to a detected value of electric **brake** torque to a calculating relay valve 9. While **electromagnetic** valves 6, 7, 8 send out liquids having pressure corresponding to the **brake** commands applied to the command lines 2, 3, 4 to the calculating relay valve 9. The calculating relay valve 9 sends out a liquid having pressure corresponding to insufficiency of **braking** force to a **brake** cylinder 10. When output of the electric **brake** becomes to zero, an electric **brake** invalid detector 15 makes the output of the electropneumatic converter 17 to zero to eliminate **hysteresis**.

ABSTRACT

PURPOSE: To enable a trolley voltage of the electric railway to be prevented from abnormally rising, by effectively absorbing regenerative powers of the electric car.

CONSTITUTION: In a thyristor switch device 7, a main thyristor 71 is controlled so as to be made in conduction when a voltage of the trolley wire rises due to the regenerative **braking** operation of an electric car. In this way, a **charging** current flows from the trolley wire to a storage battery 5. A rectifier device 6 can be operated by closing an **electromagnetic** switch 66 when the electric car is in operation of the power running. The device, feeding the power to the electric car cooperatively with railway rectifier devices 2, 2', causes the reception of AC power to moderate its peak.

JP 2003528260 W 30 F16D-051/20 Based on patent WO 200114164

Abstract (Basic): WO 200114164 A1

NOVELTY - The **electromagnetically** released **brake** (20) includes a magnet shell (26) disposed about a first axis with a radially extending pole (80,82) around which an armature (38,30) is disposed, and biased radially outwardly by a spring (36,38). The **brake** also includes a bobbin (44,46) having a flange (122) extending radially inwardly relative to a second axis and a projection (120) extending axially relative to the second axis, the flange and projection being configured to engage the magnet shell and prevent radial and axial movement of the bobbin and coil.

DETAILED DESCRIPTION - The **brake** includes the magnet shell disposed about a first axis, the armature disposed radially outwardly of the radially extending pole and pivoting at a first axial end and a first engagement element, such as a **brake** shoe, coupled to the armature proximate a second axial end of the armature. The spring disposed about the pole biases the armature radially outwardly to urge the first engagement element towards a second engagement element such as a friction surface in a **brake** drum. A coil (40,42) is disposed about the pole and selectively **energized** to urge the armature radially inwardly and the first engagement element away from the second engagement element. The **brake** also includes the bobbin having a cylindrical body portion (112) disposed about a second axis and first and second discs (118) extending radially outwardly from first and second ends, respectively, of the body portion. The bobbin further includes the flange extending radially inwardly relative to the second axis and the projection extending axially relative to the second axis, the flange and projection are configured to engage the magnet shell and prevent radial and axial movement of the bobbin and coil.

An INDEPENDENT CLAIM is included for an **electromagnetic** assembly incorporating the coil bobbin.

USE - **Brake** can be used in connection with a servomotor or stepper motor, but also in a variety of motors in a wide variety of applications (not detailed).

ADVANTAGE - **Brake** requires a relatively small amount of current to release and the amount of backlash when the **brake** is set is reduced. Coil bobbin used in **brake** or other **electromagnetic** assembly restricts movement of bobbin and coil retained by bobbin without requiring bonding to a magnet pole or other structure within the assembly.

DESCRIPTION OF DRAWING(S) - The drawing shows a cross-sectional view of the **brake** .

Abstract (Basic): JP 2000220674 A

NOVELTY - A damping board (4) is slidably mounted axially on a revolving shaft. The gap between armature and damping board lining is made small. Opposing the end face of boss element (4b) of damping board, an annular groove (8b) is provided. During **brake** release, the baffle plate is arranged opposing the annular groove such that an elastic element in annular groove contacts the end face of the baffle plate.

DETAILED DESCRIPTION - A damping spring (5) energizes the damping board in the opposite direction. A cylindrical element adjusts the stroke length of the damping board.

USE - For **electromagnetic brake** .

ADVANTAGE - Provision of elastic element in annular groove reduces noise without increasing the forming accuracy. The impact noise during armature colliding with the lining can be reduced, thereby sound-proof is reliably carried out.

DESCRIPTION OF DRAWING(S) - The figure shows the functional sectional view of the **electromagnetic brake** .

Abstract (Basic): JP 11275705 A

NOVELTY - A control unit (10) **energizes an electromagnetic brake** (22) intermittently, at the time of emergency shut-down and sends a damping command to another control unit (17). The control unit (17) controls the damping of rotations of drive motor (1).

USE - For electric sheet chair.

ADVANTAGE - A quick stoppage of the electric wheel chair is obtained. DESCRIPTION OF DRAWING(S) - The figure shows the control block diagram of the control apparatus for electric vehicle. (1) Drive motor; (10,17) Control unit; (22) **Electromagnetic brake**.

Abstract (Basic): DE 19801334 A1

NOVELTY - The **electromagnetic hysteresis brake** has at least one permanent magnet (5) near the magnet coil (4). It is deployed so that the magnetic field in the air gap (6) is formed by the combination of the magnetic flows of the **electromagnet** (4) and the permanent magnet (5). The magnetic flow of the **electromagnet** (4) is set by a value and by the polarity, so that it works with or against the magnetic flow of the permanent magnet.

DETAILED DESCRIPTION - The permanent magnet (5) is structured to deliver a **braking** torque of about 50% of the max. **braking** torque. The magnet coil (4) of the **electromagnet** is concentric within the permanent magnet (5). The magnet coil (4) of the **electromagnet** and the permanent magnet (5) can be axially in succession, with the permanent magnet next to the **hysteresis** ring (7).

USE - The **brake** assembly is especially for use as a yarn **brake** in a textile machine.

ADVANTAGE - The **brake** continues to act effectively in the event of a power supply failure, without an emergency current supply system.

DESCRIPTION OF DRAWING(S) - The drawing shows an axial section through the **hysteresis brake**.

Patent Details:

Patent No Kind Lan Pg Main IPC Filing Notes
JP 10313504 A 4 B60L-007/28

Abstract (Basic): JP 10313504 A

The control apparatus has a rotating-speed sensor (11) to detect the rotating speed of the rotating drum (47) of an electrical-eddy-current **brake** (40). When the detected rotating speed is below a predetermined value, a controller (13) reduces the amount of **energising** to the electrical-eddy-current generating coil of each **electromagnet** of the **brake**.

USE - For large-sized vehicle e.g. truck.

ADVANTAGE - Prevents overheating of coil. Damping force of **brake** can be reduced gradually since damping is not cancelled suddenly, thus operator can get good damping feeling.

Abstract (Basic): DE 4239386 A

The effect of regenerative **braking** by the traction motor is augmented by friction **brakes** applied by hydraulic pressure from a master cylinder (11) under electronic control (70). The actuating rod (6) coupled to the **brake** pedal is surrounded by a helical simulator spring (8) compressed between the end of its casing and an **electromagnet** (9) whose armature (13) surrounds the hydraulic piston rod (15).

The end of the armature impinges upon an annular flange (16) around the piston rod, causing the piston (54) to slide into the cylinder and expel fluid under pressure into the wheel **brake** lines.

ADVANTAGE - **Brake** pedal characteristic corresponds to that of standard combustion-engined car with slight **hysteresis** in interests of comfortable driving.

Abstract (Basic): DE 4235502 A

The **brake** disc (3) fixed to the axle (2) has rotor windings (5) secured near its centre in electrical contact with a brush (4) on the inside of the stator (1), whose windings (6) are arranged on both sides of the rotor (3).

A pair of friction pads (7) on the end of an electric actuator (8) are applied to the disc (3) by a control circuit (12) responsive to sensors of **brake** pedal movement (11) and road speed (15) above a min. value of the latter.

ADVANTAGE - Highly reliable system requires no piping and can be controlled with sensitivity by driver.

Patent Details:

Patent No	Kind	Lan	Pg	Main IPC	Filing Notes
SU 1678663	A1		4	B60L-007/28	

Abstract (Basic): SU 1678663 A

The system consists of a magnetic core (1) mounted on the side (2) of the waggon bogie. Between the supporting lugs of the core (1) and the side (2) there is a thin layer of diamagnetic material and the core is fixed to the sides (2) by means of staples. The core terminates in poles (N) and (S) with terminals (4) near the surface of the wheels. At each pole there is a coil (6). The ends of the coils are connected to a power line under the waggon and also to the waggon body.

In each waggon, there are emergency points with control buttons with two normally open contacts. On pressing the buttons, one pair of contacts sends power to the **electromagnetic** circuit whilst the second initiates an alarm signal and indicates to the guard, which emergency point was used. When the current is supplied to the coil (6) a circuit is created through the rails (7) and the magnetic field prevents the wheels from turning.

ADVANTAGE - Simplification of the installation. Bul.35/23.9.91.

Abstract (Basic): WO 9112657 A

Without controlling the increase or decrease of the number of **electromagnetic** coils (22) to be driven, the current control of the **electromagnetic** coils are performed including the temperature of a rotor (23) in a controlled system and thereby, environmental influence due to heat and deformation of the rotor are suppressed to the utmost. The device comprises the **electromagnetic** coils (22) provided on the stationary part side of a power feeder, the rotor (23) consisting of conductors provided on the rotating shaft side of the power feeder, switching device (24) connected to the **electromagnetic** coils, and a controller (15) for outputting switching data to the switching means on the basis of external control data.

Further, the device is constituted so that the controller controls the ON/OFF ratios of the currents flowing through the **electromagnetic** coils via the switching means. (57pp Dwg.No.4/14)%

SE 468190	B			H02K-049/02	

Abstract (Basic): DE 3542372 A

The electrical **brake** has a stator which consists of a number of separate poles of alternate polarity and a cylindrical core of ferromagnetic material carrying the winding, arranged on a carrier plate and conveniently spaced on a pitch circle of the required diameter. The carrier plate and the poles are rigidly attached to the outer bearing housing of the shaft which has to be braked. The axes of the cores point in the same direction as the shaft. The ends of the cores are closed by a shoe plate, shaped as a trapezium, and the plates can all rotate about the axis of a screw which holds a plate, core and winding to the carrier plate. The shaped plates all rotate by an eccentric peg. in unison, when the **brakes** are applied.

On the outside of the stator poles there is the induction disc of ferromagnetic material, rotating with the shaft and about the same axis and past the poles and the poles shoes, separated only by a narrow ring-shaped air gap. Normally the pole shoes are not aligned symmetrically with respect to the cores and the windings, so that they do not cover the windings, allowing the magnetic energy to escape. Most of the magnetic energy is used **braking** and **energising** of the windings and to prevent the rotation of the shaft.

ADVANTAGE - Improved **braking** moment.

Patent Details:

Patent No	Kind	Lan	Pg	Main IPC	Filing Notes
SU 818927	B		3		

Abstract (Basic): SU 818927 B

High speed rail vehicle **electromagnetic brake** has additional windings with coils perpendicular to direction of motion of the train wired into the **electromagnet** field coil circuit. The additional windings are located between the pole pieces of adjacent **electromagnets**. This reduces power consumption and variation of **braking** force by converting energy of the moving mass into electrical energy.

During **braking** the **electromagnetic brake** is brought as close as possible to the rail and electrical circuit closed. Current passes through main windings (2), additional windings (5) being de- **energised** by the diode in the circuit.

The magnetic field generated by windings (2) closes through the rail surface and generates eddy currents creating an additional magnetic field resulting in magnetised sections on the rail beyond poles (4). An e.m.f. induced in windings (5) which, when it exceeds that of the external source, or on switching of the external source, will result in main winding feed from additional windings. This will generate a field coincident with that in the pole pieces and will be unaffected by direction of travel. Bul.13/7.4.81. (3pp Dwg.No.1

Abstract (Basic): DE 2733898 A

The electrodynamic **brake** has a series of solenoid coils (2) arranged around the stator support and acting on a rotating ferromagnetic plate coupled to the drive shaft. The magnets are **energised** to provide the dynamic retardation and are themselves potted in waterproof housings.

The waterproof housings comprise plastic skins (3) with moulded ends (6) so that they can be clipped into recesses in the stator support. The dynamic **brake** is mounted on the drive shaft without any special protection for the magnets.

Priority Applications (No Type Date): US 73369502 A 19730613

Abstract (Basic): US 3866729 A

The **electromagnet** of an **electromagnetically** operated clutch or **brake** has an annular core with radial pole pieces carrying the **energising** coils, and an armature providing a pair of pole faces arranged to cooperate respectively with the ends of the pole pieces and an annular end face of the core to complete the magnetic circuit. With such an arrangement, in which the coils of the **electromagnet** are symmetrically arranged around the axis, the components of the stray magnetic field cancel one another out. This prevents such problems as e.g. the collection of abrasive particles where they will do harm.

ABSTRACT

PURPOSE: To efficiently use the **power** from an **electromagnetic** type retarder that is outputted during the **braking** operation of a vehicle as the **power** supply for **charging** a battery by using a **capacitor** having a large **capacitance**.

CONSTITUTION: An output from a retarder 1 for regenerating the **power** during the **braking** operation of a vehicle is supplied to an electrical double-layer **capacitor** 5 through a rectifier 16 and a diode 52 is connected in such a direction that **charge** is led to a battery 3 from the **capacitor** 5. Therefore, the diode 52 is reversely biased under the normal condition and **power** supply from the battery 3 by self-discharge of the **capacitor** 5 is suspended, but when an engine is started, a relay B closes due to the operation of a key switch 6 and the **capacitor** 5 is **charged** by the battery 3.

JOURNAL: Section: M, Section No. 142, Vol. 06, No. 126, Pg. 60, July 10, 1982 (19820710)

ABSTRACT

PURPOSE: To detect a **braking** condition through plugging accurately by determining reference voltage from a current detecting means by currents flowing under a locking condition of a motor during the operating time of a monostable multivibrator.

CONSTITUTION: When a switch not shown is changed over, **electromagnetic** contactors 5, 6 are each switched to the constantly-closed contact b side and the constantly-opened contact c side, and brought to plugging conditions, and currents by electromotive force flow through armature winding 3 through a plugging diode 7. In this case, the output of a comparator 20 is (1) because the **charging** voltage of a soft start **capacitor** 18 is small - that is, a conduction ratio is smaller than set value - due to the functioning of a clear circuit, etc. not shown responding to the action of a changeover switch owing to just after changing over. Since the magnitude of source currents during the operating period of the monostable multivibrator 16 becomes larger than reference value on account of the short circuit of the armature winding 3 by the

diode 7 at the same time, the output of comparators 13, 49 is both (1), base currents are supplied to a transistor 51 and the transistor 51 is at on; and plugging can be detected.

ABSTRACT

PURPOSE: To precisely detect plugging **brake** condition without being affected by variations in temperature and **power** voltage, by a method wherein commutating **capacitor** voltage at the time of interrupting a thyristor chopper circuit is detected and the conductive rate of the chopper circuit is also detected.

CONSTITUTION: With **electromagnetic** contactors 3, 4 changed over at $t=0$, the voltage at the output point C of a reset soft start circuit 9 rises from the minimum value as shown in i, namely, the conductive rate of a chopper 1 also rises. The voltage at the output point B of a reference signal circuit 11 is decided by the voltage at a point C and the input voltage in a plugging detection circuit 14 decreases as shown in ii, plugging **brake** starts at $t=t(\text{sub } 4)$ and when an armature winding 2b is in the short-circuit condition, the **charge** voltage of a commutating **capacitor** 1d rises and the voltage after a vibrating phenomenon becomes more lower. Namely, the voltage (input voltage of the circuit 14) at the output point A in a **capacitor** voltage detector 12 at the time of interrupting the chopper 1 becomes lower than ii at $t=t(\text{sub } 4)$ as shown in iii, accordingly, detection is made to know that the circuit 14 is under plugging **brake** to act to decrease the electric potential at a point E and the conductive rate of the chopper 1 is controlled so as to be lower.

Abstract (Basic): WO 200066388 A1

NOVELTY - The energy accumulation and recuperation of vehicle are done, in points of electric contact system using **capacitor** bank, during motion and **braking** of motor vehicle.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for the energy accumulation and recuperation device.

USE - For energy accumulation and recuperation in different types of motor vehicles (MV) driven by electric motors or in combination with hybrid motor vehicles such as electric cars, trolley busses, trams, electric train.

ADVANTAGE - The **capacitor** fitness is not determined by number of **charge** -discharge cycles, as a result of which they are very much more durable than the accumulators. The efficiency of capacitors is much higher than that of accumulators and is equal to nearly 100%. Unlike the accumulators and fuel cells, capacitors can be **charged** and discharged exceptionally quickly for less than a second, which enables giving-off and intake of large currents towards and from the drive electric motors which in turn ensures great acceleration of the MV, without need of increasing the **power** of energy source. By using capacitors, starting and reaching maximum speed are achieved without prior switching-ON of primary **power** source of motor vehicle. Enables greater freedom and maneuverability of the motor vehicle fed by electric contact systems, thereby reduces energy consumption for motor vehicle motion. Facilitates to remove the electric contact system above the basic part of route and replace it with separate points thereby avoids limitations concerning the height of transported cargo, thereby puts and end to spoiling the look of streets and squares with hanging electric contact system. The electric contact system is situated under the ground, thus it is naturally shielded and also additionally shielded through metal cover of cables thus avoiding **electromagnetic** pollution.

DESCRIPTION OF DRAWING(S) - The figure shows the perspective diagram explaining connection in case of two wires of electric contact system situated transversely on the road.

ABSTRACT

PURPOSE: To carry out smooth traveling by controlling the rotational speed of a motor based on a speed obtained from the operating amount of accelerator pedal and a **brake** amount obtained from the operating amount of **brake** lever and applying **electromagnetic brake** if the **brake** amount is higher than a predetermined level.

CONSTITUTION: Operating amount of accelerator pedal is detected through a variable **resistor** 21 in order to detect 16 a speed amount which is then

fed to a speed control circuit 18. Operating amount of **brake** lever is detected through a variable **resistor** 22 and then fed through a **brake** amount decision circuit 19 to a speed control circuit 18. When the output from the **brake** amount detecting circuit 17 exceeds a predetermined level, the **brake** amount decision circuit 19 makes a switching to an **electromagnetic brake** 20 which then delivers an output to the speed control circuit 18. The speed control circuit 18 controls rotation of a motor 2 based on the speed amount and the **brake** amount. Consequently, smooth traveling is realized and safety is enhanced.

24, 1992 (19920624)

ABSTRACT

PURPOSE: To adjust the currents of an **electromagnet** and to keep damping torque set by rotatably supporting a magnet support plate supporting the **electromagnet** to the fixed shaft of a **brake** disc against resilient force and mounting a rheostat operated by relative rotation between the fixed shaft and the magnet support plate.

CONSTITUTION: When a switch 3 is closed when a **brake** disc 11 is turned, **electromagnets** 6 are excited, and damping torque is obtained by the eddy currents of the **brake** disc 11. Torque reaction reverse to the direction of rotation received by a magnet support plate 5 is supported by a fixed shaft 12 through springs 13. When actual damping torque is larger than a set value, the magnet support plate 5 is rotated in the direction opposite to the direction of rotation against the force of the springs 13, relative rotational displacement is generated between a sliding resistor 7 and an armature 10a, and the **resistance** value of the **resistor** 7 is increased. The **electromagnetic** force of the **electromagnets** 6 is weakened, and damping torque is set at positions where damping torque set by the armature 10a and the springs 13 supporting torque reaction received by the magnet support plate 5 balance. Accordingly, damping torque required is given to the **brake** disc 11, and damping torque is kept at the set value.

ABSTRACT

PURPOSE: To sustain effective function of generative **brake** even in low speed region by increasing the **resistance** of a **brake resistor** when the running speed makes a transition from high speed region to low speed region through generative **brake** operation.

CONSTITUTION: Generative **brake** resistors R1, R2 consume DC power fed from an inverter 7 side and produce **brake** force. Generative **brake** functions upon closure of an **electromagnetic** contactor 15. When the running speed of an electric rolling stock exceeds a predetermined level, an **electromagnetic** contactor 15 short-circuits the **resistor** R2. Consequently, **brake resistance** is decreased for a high running speed whereas it is increased for a low running speed. By such arrangement, the inverter 7 can be operated upto the low rotation region of an induction motor 9.

ABSTRACT

PURPOSE: To operate an alarm bell and an emergency **brake** instantaneously by changing the frequency of a receiver to that of a second ground unit through an onboard unit when a train passes through the second ground unit even if the train starts erroneously.

CONSTITUTION: When a train stopped at a position in front of a signal

passes through a second ground unit, the second ground unit operating with frequency of 123kHz is coupled **electromagnetically** with an onboard unit 5, and the oscillation frequency of a receiver 6 is changed from 105kHz to 123kHz which is the resonance frequency of the second ground unit. A relay ECR functions upon tripping of a relay MR based on the changed frequency while simultaneously a **capacitor** connected in parallel with a relay UR is separated through the functioned contact of a relay ECBR upon tripping thereof. When an alarm bell is sounded through a relay MPR which trips simultaneously with the relay MR and the relay ECBR and the relay UR is tripped simultaneously, an emergency **brake** can be operated simultaneously.

ABSTRACT

PURPOSE: To detect the plugging operation precisely by providing the current detecting circuit which detects the difference between the current flowing via a field winding and the current flowing in a plugging diode and employing the output of this circuit.

CONSTITUTION: When the output value (the potential at a point C) of a differential amplifier 12 which amplifies the output signal of the current detecting circuit 11 becomes the value lower than the plugging detecting level, a comparator 25 detects the plugging **brake** . A **capacitor** 24 is discharged through a **resistor** 31, and the increase in the difference

between the current IF flowing in a field winding 2 and the current IP flowing in a plugging diode 7 can be prevented. When the potential at the point C reaches the set value (overcurrent limiting value) in the current limiting circuit 32, a chopper 1 is cut off by a chopper control circuit 10. Furthermore, when the plugging diode 7 is shorted and failed, the failure is detected by a shorting failure detecting circuit 33, a transistor 40 is cut off, and the main circuit is stopped by the operation of an **electromagnetic** contactor 5.

ABSTRACT

PURPOSE: To suppress voltage increase by connecting a flywheel thyristor in parallel with a series circuit consisting of a main field coil and a main smoothing reactor such that it is fired upon detection of an increase of the input **capacitor** voltage at the time of loss of the regenerative load.

CONSTITUTION: When the regenerative load is lost during the regenerative **braking**, the voltage across an input **capacitor** 1 is increased to fire a flywheel thyristor 11, whereby **electromagnetic** energy stored in the main field coil and main smoothing reactor is circulated through the thyristor switch to prevent the load current from flowing into the filter **capacitor** so as to suppress the voltage increase.

Abstract (Basic): US 20030094337 A1

NOVELTY - An **electromagnet** (120) comprises a polymer impregnated powder metal core containing a coil. The powder metal core has a Young's modulus of elasticity of 6.8-29.5 million psi.

DETAILED DESCRIPTION - An **electromagnet** comprises a polymer impregnated powder metal core containing a coil; and an injection molding material attached to the powder metal core. The powder metal core has a Young's modulus of elasticity of 6.8-29.5 million psi. The injection molding material comprises a donor material having an elasticity greater than 2 million psi that provides a hard protective wear resistant surface layer, a composite adhering coating layer and an interior layer that has the ability to act in concert with shearing of the composite adhering coating.

USE - Used in an electrically actuated vehicle **brake**.

ADVANTAGE - The invention has less variance between units, increased frictional drag, reduced wear and the **brake** drum disk during use and has an increased **resistance** to moisture. It also withstand at much higher surface speeds while producing higher frictional drag.

DESCRIPTION OF DRAWING(S) - The figure is an elevational view of a drum **brake** assembly.

Abstract (Basic): JP 2002369304 A

NOVELTY - The controller connects a **capacitor** or a secondary battery, in series with the input terminal of electric **power** converter, such that the voltage application direction of **capacitor** or secondary battery (Vc) is the same as that of the DC **power** source (Va) (1), when the regenerative **brake power** is below a prescribed value.

USE - Especially for regenerative **brake** control of electric vehicle such as electric train.

ADVANTAGE - Improves the effectiveness of regeneration energy and enables achievement of necessary **brake** -force characteristics, using simple technique. Reduces the generation of **electromagnetic** sound.

DESCRIPTION OF DRAWING(S) - The figure shows a block diagram of the electric vehicle controller.

Abstract (Basic): JP 9322311 A

The device includes an output shaft (56) which is rotated by a prime mover (50). A pair of outer and inner rotors (32,34) of a clutch electric motor (30) are coupled with the output shaft and a drive shaft (22) respectively. The clutch motor exchanges **power** between the output shaft and the drive shaft, through an **electromagnetic** coupling between the outer and inner rotors. The torque of the **power** output of an assistant motor (40) is transferred to the drive shaft. A first electric motor drive circuit (91) controls the relative rotary for the outer and inner rotors. A second drive circuit (92) does drive control

of the assistant motor. A battery (94) supplies electric **power**, which drives the clutch and assistant electric motors. An output shaft **braking** unit (57) retards the output shaft speed of the prime mover.

ADVANTAGE - Reduces internal pressure of prime mover. Increases movement **resistance** of prime mover and increases torque output from assistant motor.

Abstract (Basic): US 5396214 A

The dynamic **braking** grid arrangement reduces EMI generated by dynamic or partial regenerative electrical **braking** of an electric traction motor powered vehicle coupled to a wayside **power** source by a third rail or catenary. The grid arrangement comprises a high- **power** dissipation **resistance** grid having a number of separately defined

resistance elements, each having a generally elongate configuration. A mounting device supports each of the grid elements adjacent to and parallel with each other of the elements.

A number of electrical conduction devices connect the elements into an electrical circuit such that current passes through at least one element in a first direction and through at least one adjacent element in a second opposite direction such that EMI generated by any one element is cancelled by EMI generated by an adjacent element.

ADVANTAGE - Minimises induced currents in wayside conductors and rails.

Abstract (Basic): SU 1766724 A

The electrical locomotive is propelled by an electric traction motor. The motor windings (4,6) are fed by a **power** source via a current collector (2). When the current supply network becomes disturbed, then the signals of min. current and speed transducers (1,7) change the current via AND-gate (9) for the input of insertion unit (3), which connects the **braking resistor** (8) across the motor. During stoppage of the electric locomotive, the winding (4) voltage is lowered, and the winding (10) brings the **electromagnetic brake** into a working condition, and prevents the locomotive from taking up a self-propelled condition.

USE/ADVANTAGE - In **braking** system for electric locomotive with increased working reliability. Bul.37/07.10.92

Abstract (Basic): FR 2358774 A
The **electromagnetic braking** circuit, for large rotating machines in vehicles, has the **electromagnet** excitation coil (2) in series with a semiconductor current regulator (5) (chopper) and a protective **resistor** across the **dc** supply. The regulator is controlled by a differential amplifier (11) coupled by one input to a rheostate (13) and by its other input to the coil.
The amplifier compares the voltage characterising the disc angular **braking** with the voltage representing the max. **braking**. The amplifier controls the regulator such that the ratio of its opened/closed times diminishes if the disc **braking** exceeds the max.

Priority Applications (No Type Date): SU 1496009 A 19701125

Abstract (Basic): SU 466598 A

The regulation is precise, the utilization of the **braking** rheostat is ameliorated. The control signal is formed as a function of **electromagnetic power** difference, which is passed to the motor and the **power** required by the **braking** rheostat. Under **braking** condition of asynchronous motor (1), which is fed by a frequency converter (2), it works as a generator. It receives excitation **power** from synchronous generator (3), which acts as a synchronous compensator, driven by the diesel engine (4) and passes an active **power** to the **braking** rheostat (5). To obtain a required **braking** characteristic, the generator voltage (3) is regulated as a frequency function. The **power** dissipated in the rheostat (5) depends on the **resistance** magnitude and generator voltage.

ABSTRACT

PROBLEM TO BE SOLVED: To provide an inexpensive **brake** device for combined operation allowing a **brake** instruction transmitting time to be shortened even in the combined operation of an air car and an electric car.

SOLUTION: In an electric car side re-reader 10, a **brake** instruction for the electric car is converted into an electric signal by using a specified conversion factor, and transmitted to an air car side re-reader 9 through an electric cable 11a. The air car side re-reader 9 converts the received electric signal inversely to a target **brake** pressure value by using a specified conversion factor. Then, according to an automatic **electromagnetic brake** system, a solenoid supply and exhaust valve 8 is **energized / deenergized** so that an actual BP pressure follows the target **brake** pressure value. Also when the **brake** instruction is transmitted from the air car to the electric car, the actual BP pressure is converted to an electric signal by using the conversion factor, and the electric signal is transmitted to an electric car side via an electric cable 12a.

ABSTRACT

PURPOSE: To shorten the torqueless time following the operation stoppage of a chopper during a transitional period from regenerative **braking** to reverse rotation **braking** by shortening the transitional period as much as possible.

CONSTITUTION: A transitional period from regenerative **braking** to reverse rotation **braking** is shortened by stopping the operation of a chopper by turning of a transistor TM a fixed period after the coil MG of a regenerative **electromagnetic** switch is **energized** following the completion of the regenerative **braking** and, at the same time, starting the operation of the chopper for reverse rotation **braking** by turning on the transistor TM immediately after the closing state of a contact mg is detected by means of an operation detecting section 12.

ABSTRACT

PURPOSE: To suppress the slipping in a state that a towing force is held by detecting that the rotating speed of a wheel is a predetermined value or less and **energizing** an **electromagnetic** coil disposed oppositely to rails when a power running command is output.

CONSTITUTION: An **electromagnetic** coil 3 is mounted at a truck 2 oppositely to rails 1, and **energized** by **energizing** means 4. Speed comparing means 6 detects a rotating speed V, compares it with a set predetermined speed value Vset, and outputs a '1' signal to an AND circuit 7 when it is the value Vset or less. Then, it inputs the command from command means 5 and further inputs the outputs from the means 6, it outputs the '1' signal to an AND circuit 8. Then, when the circuit 8 inputs the '1' signal, it outputs a close signal to a switching circuit 4. The circuit 8 outputs the close signal to the circuit 4 even when it inputs the emergency **brake** command B from the means 5. Thus, the slipping at a low speed at the time of power running can be effectively prevented.

ABSTRACT

PURPOSE: To enhance generation efficiency or fuel consumption by

interposing a retarder for recovering power **electromagnetically** from **brake** energy between a clutch and a speed change gear.

CONSTITUTION: Rotor 3 of retarder 2 is coupled with the output shaft of a clutch 13 for transmitting/interrupting engine torque, and a field section 41 is disposed on the inside of outer peripheral poles 31, 32 whereas an armature 4 is disposed on the outside thereof. When a vehicle is braked, the field section 41 is conducted to excite the poles 31, 32 thus taking out **brake** power from the armature 4. When the engine is started or accelerated, the field section 41 and the armature 4 are conducted to drive the retarder 2 through a motor thus **energizing** engine torque.

JOURNAL: Section: M, Section No. 1123, Vol. 15, No. 228, Pg. 160, June 11, 1991 (19910611)

ABSTRACT

PURPOSE: To prolong the running distance of an electric automobile for one **charge** of a battery by a method wherein the shortage of a **braking** force obtained by regenerative **braking** and hydraulic **braking** against an instructed **braking** force is filled with a **braking** force supplied from an **electromagnetic braking** apparatus.

CONSTITUTION: In order to **brake** an electric automobile, a controller 20 determines a necessary **braking** force FA in accordance with the magnitude of a **brake** signal. On the other hand, the controller 20 obtains the **charging** status of a battery and determines the magnitude of a regenerative **braking** force in accordance with the **charging** status. Then a chopper circuit 22 is controlled by the controller 20 in accordance with a force value obtained by reducing the regenerative **braking** force and the hydraulic **braking** force of a hydraulic **braking** apparatus from the necessary **braking** force. Therefore, an **electromagnetic brake** 24 generates a **braking** force which is determined by the controller 20 and the chopper circuit 22 in accordance with the necessary **braking** force and the regenerative force and **brakes** wheels through a decelerating mechanism 12 and a wheel shaft 10.

ABSTRACT

PURPOSE: To complete accurately insufficiency of electric **braking** force with **braking** force of a liquid **brake** in the **braking** device of the rolling stock car by a method wherein when an electric **brake** becomes to invalid, output liquid pressure of an electropneumatic converter is made to zero.

CONSTITUTION: **Braking** commands applied to command lines 2, 3, 4 are transmitted to an electric **brake** equipment 13 through a D-A converter 12. The electropneumatic converter sends out a liquid having pressure corresponding to a detected value of electric **brake** torque to a calculating relay valve 9. While **electromagnetic** valves 6, 7, 8 send out liquids having pressure corresponding to the **brake** commands applied to the command lines 2, 3, 4 to the calculating relay valve 9. The calculating relay valve 9 sends out a liquid having pressure corresponding to insufficiency of **braking** force to a **brake** cylinder 10. When output of the electric **brake** becomes to zero, an electric **brake** invalid detector 15 makes the output of the electropneumatic converter 17 to zero to eliminate **hysteresis**.

ABSTRACT

PURPOSE: To enable a trolley voltage of the electric railway to be

prevented from abnormally rising, by effectively absorbing regenerative powers of the electric car.

CONSTITUTION: In a thyristor switch device 7, a main thyristor 71 is controlled so as to be made in conduction when a voltage of the trolley wire rises due to the regenerative **braking** operation of an electric car. In this way, a **charging** current flows from the trolley wire to a storage battery 5. A rectifier device 6 can be operated by closing an **electromagnetic** switch 66 when the electric car is in operation of the power running. The device, feeding the power to the electric car cooperatively with railway rectifier devices 2, 2', causes the reception of AC power to moderate its peak.

JP 2003528260 W 30 F16D-051/20 Based on patent WO 200114164

Abstract (Basic): WO 200114164 A1

NOVELTY - The **electromagnetically** released **brake** (20) includes a magnet shell (26) disposed about a first axis with a radially extending pole (80,82) around which an armature (38,30) is disposed, and biased radially outwardly by a spring (36,38). The **brake** also includes a bobbin (44,46) having a flange (122) extending radially inwardly relative to a second axis and a projection (120) extending axially relative to the second axis, the flange and projection being configured to engage the magnet shell and prevent radial and axial movement of the bobbin and coil.

DETAILED DESCRIPTION - The **brake** includes the magnet shell disposed about a first axis, the armature disposed radially outwardly

of the radially extending pole and pivoting at a first axial end and a first engagement element, such as a **brake** shoe, coupled to the armature proximate a second axial end of the armature. The spring disposed about the pole biases the armature radially outwardly to urge the first engagement element towards a second engagement element such as a friction surface in a **brake** drum. A coil (40,42) is disposed about the pole and selectively **energized** to urge the armature radially inwardly and the first engagement element away from the second engagement element. The **brake** also includes the bobbin having a cylindrical body portion (112) disposed about a second axis and first and second discs (118) extending radially outwardly from first and second ends, respectively, of the body portion. The bobbin further includes the flange extending radially inwardly relative to the second axis and the projection extending axially relative to the second axis, the flange and projection are configured to engage the magnet shell and prevent radial and axial movement of the bobbin and coil.

An INDEPENDENT CLAIM is included for an **electromagnetic** assembly incorporating the coil bobbin.

USE - **Brake** can be used in connection with a servomotor or stepper motor, but also in a variety of motors in a wide variety of applications (not detailed).

ADVANTAGE - **Brake** requires a relatively small amount of current to release and the amount of backlash when the **brake** is set is reduced. Coil bobbin used in **brake** or other **electromagnetic** assembly restricts movement of bobbin and coil retained by bobbin without requiring bonding to a magnet pole or other structure within the assembly.

DESCRIPTION OF DRAWING(S) - The drawing shows a cross-sectional view of the **brake**.

Abstract (Basic): JP 2000220674 A

NOVELTY - A damping board (4) is slidably mounted axially on a revolving shaft. The gap between armature and damping board lining is made small. Opposing the end face of boss element (4b) of damping board, an annular groove (8b) is provided. During **brake** release, the baffle plate is arranged opposing the annular groove such that an elastic element in annular groove contacts the end face of the baffle plate.

DETAILED DESCRIPTION - A damping spring (5) energizes the damping board in the opposite direction. A cylindrical element adjusts the stroke length of the damping board.

USE - For **electromagnetic brake** .

ADVANTAGE - Provision of elastic element in annular groove reduces noise without increasing the forming accuracy. The impact noise during armature colliding with the lining can be reduced, thereby sound-proof is reliably carried out.

DESCRIPTION OF DRAWING(S) - The figure shows the functional sectional view of the **electromagnetic brake** .

Title: Optimizing electromechanical brakes

Abstract: The influence of various parameters of electromechanical **brakes** on their dynamic characteristics in various operating conditions is investigated. Recommendations are made to permit minimization of the dimensions, **power** consumption, and copper consumption, with the specified initial data. The results may be used in the design of various mechanisms based on an **electromagnetic** system with a mobile armature. 6 Refs.

A Fuzzy Logic Controlled Braking Resistor Scheme for Damping Shaft Torsional Oscillations

ABSTRACT: This paper presents a fuzzy logic switching for the thyristor controlled **braking resistor** to damp turbine-generator shaft torsional oscillations. Following a major disturbance in electric **power** system, variable rotor speed of the generator is measured, and then the current through the **braking resistor** is controlled by the firing-angle of the thyristor switch which is controlled by the fuzzy logic. Thus the **braking resistor** controls the accelerating **power** in generators and damps the shaft torsional oscillations. The effects of the fault occurring time on turbine shaft torsional torques have also been investigated. Simulations are performed by using EMTP (**Electro - Magnetic** Transients Program). Through the simulation results of various multi-phase faults in a single machine connected to an infinite bus system, the effectiveness of the proposed fuzzy logic controlled **braking resistor** in damping shaft torsional oscillations is demonstrated. Stabilized control of electric power system using superconducting magnetic energy storage system (SMES) combined with braking resistor

ABSTRACT: The authors proposed a new control system which enables effective stabilized control of electric **power** system through the combined use of an SMES and a **braking resistor**. This control system can provide a determination process of combination of individual capacities required for stabilizing a given electric **power** system. It was also confirmed from the simulation that the control system showed a constant

Drive DC bus voltage control during power interruptions using kinetic energy recovery

ABSTRACT:

...a total loss of system control since the control electronics are usually powered by the **DC -link capacitor** , requiring a full restart. The proposed solution to this problem is to recover some of...

...kinetic buffering. During the interruption interval, the drive system continues to operate at almost zero **electromagnetic** torque, just regenerating a minor amount of **power** to cover the electrical losses in the inverter. The still controlled **braking** of the drive depends on the available load torque. Thus, the implemented regenerative **braking** scheme allows the inverter to keep its **DC bus voltage** at a predetermined minimum level, expanding the time during which the supply voltage can be reapplied without the time-consuming **DC -link capacitor** recharging cycle.

Considering realistic conditions, advantages and drawbacks of different control approaches are discussed. Measured...

Document type: journal article Language: English

Record type: Abstract

ISSN: 1344-7653

Suppressing the blade vibrations of a turbine-generator due to power disturbances by optimally operating a BR bank

ABSTRACT:

This paper proposes an operating mode of a BR (**braking resistor**) bank, which was originally installed in generation system to promote the stability as well as improve the transient response, to suppress turbine blade vibrations arising from **power** system faults. Because most of cumulative blade damages are produced in the beginning cycles, this...
...BR bank about a cycle time is adequate to effectively restrict the peak system-frequency **electromagnetic** disturbing torques. Since the system-frequency responses always play an essential role on blade vibration behaviors arising from **power** system disturbances, vibrations can be significantly suppressed accordingly. The BR bank is activated at the instant of **power** system disturbances, it will dissipate only small amount of energy.

ABSTRACT:

...s applied MHD technology is the control of molten steel flow in the mold by **electromagnetic** stirring and **braking**. In this paper, features of these flow control techniques are described from a MHD point of view. Also introduced are some of the characteristic metallurgical benefits of **electromagnetic** stirring and **braking** confirmed by plant tests. Further, description is made of the technique of controlling the initial solidification of steel in the mold by an **alternating - current** magnetic field that has been attracting increasing attention in recent years, according to the results...

...and steel casting test. Application of MHD in the continuous casting process started with the **electromagnetic** stirring of stand pool with a traveling magnetic field. It has now advanced to the **electromagnetic** stirring of molten steel in the mold and the control of molten steel flow by an in-mold **DC** magnetic field **brake**. These applied MHD techniques are designed to further improve the continuous casting process capability. They...

...and promoting the flotation of argon bubbles. A new concept of initial solidification control by **AC** magnetic field has been proposed, which decreases the surface roughness or the depth of oscillation marks on the cast billet and the withdrawal **resistance** in the mold to simultaneously achieve the high productivity and the high surface quality.

Abstract (Basic): JP 11275705 A

NOVELTY - A control unit (10) **energizes** an **electromagnetic brake** (22) intermittently, at the time of emergency shut-down and sends a damping command to another control unit (17). The control unit (17) controls the damping of rotations of drive motor (1).

USE - For electric sheet chair.

ADVANTAGE - A quick stoppage of the electric wheel chair is obtained. DESCRIPTION OF DRAWING(S) - The figure shows the control block diagram of the control apparatus for electric vehicle. (1) Drive motor; (10,17) Control unit; (22) **Electromagnetic brake** .

Abstract (Basic): DE 19801334 A1

NOVELTY - The **electromagnetic hysteresis brake** has at least one permanent magnet (5) near the magnet coil (4). It is deployed so that the magnetic field in the air gap (6) is formed by the combination

of the magnetic flows of the **electromagnet** (4) and the permanent magnet (5). The magnetic flow of the **electromagnet** (4) is set by a value and by the polarity, so that it works with or against the magnetic flow of the permanent magnet.

DETAILED DESCRIPTION - The permanent magnet (5) is structured to deliver a **braking** torque of about 50% of the max. **braking** torque. The magnet coil (4) of the **electromagnet** is concentric within the permanent magnet (5). The magnet coil (4) of the **electromagnet** and the permanent magnet (5) can be axially in succession, with the permanent magnet next to the **hysteresis** ring (7).

USE - The **brake** assembly is especially for use as a yarn **brake** in a textile machine.

ADVANTAGE - The **brake** continues to act effectively in the event of a power supply failure, without an emergency current supply system.

DESCRIPTION OF DRAWING(S) - The drawing shows an axial section through the **hysteresis brake**.

magnet coil (4)

permanent magnet (5)

air gap (6)

hysteresis ring (7)

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 10313504	A	4	B60L-007/28	

Abstract (Basic): JP 10313504 A

The control apparatus has a rotating-speed sensor (11) to detect the rotating speed of the rotating drum (47) of an electrical-eddy-current **brake** (40). When the detected rotating speed is below a predetermined value, a controller (13) reduces the amount of **energising** to the electrical-eddy-current generating coil of each **electromagnet** of the **brake**.

USE - For large-sized vehicle e.g. truck.

ADVANTAGE - Prevents overheating of coil. Damping force of **brake** can be reduced gradually since damping is not cancelled suddenly, thus operator can get good damping feeling.

Patent No	Kind	Lan	Pg	Main IPC	Filing Notes
JP 10313503	A		5	B60L-007/28	

Abstract (Basic): JP 10313503 A

The control apparatus has a temperature sensor (11) which detects the temperature of an electrical-eddy current generating coil (51a,55a) of each **electromagnet** (51,58) of the electrical-eddy-current **brake** (40). When the detected temperature exceeds a predetermined value, an **energising** restraining device (12) reduces the amount of **energising** to each coil.

USE - For large-sized vehicle e.g. truck.

ADVANTAGE - Prevents overheating of coil. Enables operator to correspond to variation of damping force since damping force can be reduced gradually.

FR 2698331	A1			B60T-007/06	

Abstract (Basic): DE 4239386 A

The effect of regenerative **braking** by the traction motor is augmented by friction **brakes** applied by hydraulic pressure from a master cylinder (11) under electronic control (70). The actuating rod (6) coupled to the **brake** pedal is surrounded by a helical simulator spring (8) compressed between the end of its casing and an **electromagnet** (9) whose armature (13) surrounds the hydraulic piston rod (15).

The end of the armature impinges upon an annular flange (16) around the piston rod, causing the piston (54) to slide into the cylinder and expel fluid under pressure into the wheel **brake** lines.

ADVANTAGE - **Brake** pedal characteristic corresponds to that of standard combustion-engined car with slight **hysteresis** in interests of comfortable driving.

Patent Details:

Patent No: Kind Lan Pg Main IPC Filing Notes
SU 1678663 A1 4 B60L-007/28

Abstract (Basic): SU 1678663 A

The system consists of a magnetic core (1) mounted on the side (2) of the waggon bogie. Between the supporting lugs of the core (1) and the side (2) there is a thin layer of diamagnetic material and the core is fixed to the sides (2) by means of staples. The core terminates in poles (N) and (S) with terminals (4) near the surface of the wheels. At each pole there is a coil (6). The ends of the coils are connected to a power line under the waggon and also to the waggon body.

In each waggon, there are emergency points with control buttons with two normally open contacts. On pressing the buttons, one pair of contacts sends power to the **electromagnetic** circuit whilst the second initiates an alarm signal and indicates to the guard, which emergency point was used. When the current is supplied to the coil (6) a circuit is created through the rails (7) and the magnetic field prevents the wheels from turning.

ADVANTAGE - Simplification of the installation. Bul.35/23.9.91.

Abstract (Basic): WO 9112657 A

Without controlling the increase or decrease of the number of **electromagnetic** coils (22) to be driven, the current control of the **electromagnetic** coils are performed including the temperature of a rotor (23) in a controlled system and thereby, environmental influence due to heat and deformation of the rotor are suppressed to the utmost. The device comprises the **electromagnetic** coils (22) provided on the stationary part side of a power feeder, the rotor (23) consisting of conductors provided on the rotating shaft side of the power feeder, switching device (24) connected to the **electromagnetic** coils, and a controller (15) for outputting switching data to the switching means on the basis of external control data.

Further, the device is constituted so that the controller controls the ON/OFF ratios of the currents flowing through the **electromagnetic** coils via the switching means. (57pp Dwg.No.4/14)%

Abstract (Basic): DE 3542372 A

The electrical **brake** has a stator which consists of a number of separate poles of alternate polarity and a cylindrical core of ferromagnetic material carrying the winding, arranged on a carrier plate and conveniently spaced on a pitch circle of the required diameter. The carrier plate and the poles are rigidly attached to the outer bearing housing of the shaft which has to be braked. The axes of the cores point in the same direction as the shaft. The ends of the cores are closed by a shoe plate, shaped as a trapezium, and the plates can all rotate about the axis of a screw which holds a plate, core and winding to the carrier plate. The shaped plates all rotate by an eccentric peg. in unison, when the **brakes** are applied.

On the outside of the stator poles there is the induction disc of ferromagnetic material, rotating with the shaft and about the same axis and past the poles and the pole shoes, separated only by a narrow ring-shaped air gap. Normally the pole shoes are not aligned symmetrically with respect to the cores and the windings, so that they do not cover the windings, allowing the magnetic energy to escape. Most of the magnetic energy is used **braking** and **energising** of the windings and to prevent the rotation of the shaft.

ADVANTAGE - Improved **braking** moment.

Patent Details:

Patent No	Kind	Lan	Pg	Main IPC	Filing Notes
-----------	------	-----	----	----------	--------------

Abstract (Basic): SU 818927 B

High speed rail vehicle **electromagnetic brake** has additional windings with coils perpendicular to direction of motion of the train wired into the **electromagnet** field coil circuit. The additional windings are located between the pole pieces of adjacent **electromagnets**. This reduces power consumption and variation of **braking** force by converting energy of the moving mass into electrical energy.

During **braking** the **electromagnetic brake** is brought as close as possible to the rail and electrical circuit closed. Current passes through main windings (2), additional windings (5) being de- **energised** by the diode in the circuit.

The magnetic field generated by windings (2) closes through the rail surface and generates eddy currents creating an additional magnetic field resulting in magnetised sections on the rail beyond poles (4). An e.m.f. induced in windings (5) which, when it exceeds that of the external source, or on switching of the external source, will result in main winding feed from additional windings. This will generate a field coincident with that in the pole pieces and will be unaffected by direction of travel. Bul.13/7.4.81. (3pp Dwg.No.1

Abstract (Basic): DE 2733898 A

The electrodynamic **brake** has a series of solenoid coils (2) arranged around the stator support and acting on a rotating ferromagnetic plate coupled to the drive shaft. The magnets are **energised** to provide the dynamic retardation and are themselves potted in waterproof housings.

The waterproof housings comprise plastic skins (3) with moulded

ends (6) so that they can be clipped into recesses in the stator support. The dynamic **brake** is mounted on the drive shaft without any special protection for the magnets.

Title Terms: EDDY; CURRENT; **BRAKE** ; ASSEMBLE; **ELECTROMAGNET** ; HERMETIC; SEAL; SOLENOID; CLIP; **BRAKE** ; HOLD

WPI Acc No: 1975-C4793W/197509

Electromagnetic operated clutches and brakes - stray magnetic fields are minimised using toroidal shape magnetic field

Patent Assignee: AUTOMATIC RES DEV (AUTO-N)

Number of Countries: 001 Number of Patents: 001

Patent Family:

Patent No	Kind	Date	Applicat No	Kind	Date	Week
US 3866729	A	19750218				197509 B

Priority Applications (No Type Date): US 73369502 A 19730613

Abstract (Basic): US 3866729 A

The **electromagnet** of an **electromagnetically** operated clutch or **brake** has an annular core with radial pole pieces carrying the **energising** coils, and an armature providing a pair of pole faces arranged to cooperate respectively with the ends of the pole pieces and an annular end face of the core to complete the magnetic circuit. With such an arrangement, in which the coils of the **electromagnet** are symmetrically arranged around the axis, the components of the stray magnetic field cancel one another out. This prevents such problems as e.g. the collection of abrasive particles where they will do harm.

Resume:

L'invention propose un groupe motopropulseur, comportant un moteur thermique (12) dote d'un systeme (14) d'injection et de soupapes commandes par une unite (18) de commande asservie par une pedale (36) d'accelerateur, et du type dans lequel un module electronique (34) pilote un alternateur (26) et l'unite (18) pour controler le systeme (14) d'injection et les soupapes, pour etabliir, en reponse au lacher de la pedale (36), une configuration determinee selon laquelle le systeme d'injection (14) est inactif et les soupapes sont ouvertes pour reduire le frein moteur, caracterise en ce que le module electronique (34) peut, dans la configuration determinee, etabliir un mode de recuperation de puissance en deceleration dans lequel, en fonction d'un bilan de valeurs de puissances mecaniques et/ ou electriques pouvant etre echangees dans l'ensemble du groupe motopropulseur, le module electronique (34) pilote l'unite (18) de commande du moteur pour ouvrir les soupapes et commander la **charge** de la batterie (32) de stockage.
